

Silicon materials are used in optical fiber communication

These fibers, primarily composed of silicon dioxide (SiO_2), offer exceptional thermal stability, low attenuation, and high resistance to radiation, making them indispensable in aerospace, ...

Silica fibers dominate many applications, such as optical fiber communications (except for very short distances with plastic optical fibers), most fiber lasers and amplifiers, and fiber-optic sensors.

Silicon photonic devices can be made using existing semiconductor fabrication techniques, and because silicon is already used as the substrate for most integrated circuits, it is possible to create hybrid ...

Not only does silicon have a high refractive index, making it an excellent material for fiber-optic communications, but its processing is also well-established, allowing for easy integration of ...

We describe how silicon photonic circuits can be used to perform unitary matrix operations and unscramble the different data lanes in multichannel optical communication systems.

Optical fibers are composed primarily of silicon dioxide (SiO_2), though minute amounts of other chemicals are often added.

Silicon is the material that has dominated the creation of fiber optics for the telecommunications industry. Silicon-based fiber optic cables (normally silicon dioxide) are also...

In this chapter, we will introduce the development history, manufacturing, optical properties, and applications of silicon-based optical fibre in detail.

This tutorial reviews silicon core fibers: a platform that unites fiber optics and silicon photonics.

Silicon fiber uses a core made of highly crystalline silicon, a semiconductor material, encased within a silica glass cladding. Because the core is a semiconductor, the fiber can both guide ...
